Andere auf der Liste konzentrieren sich darauf, wer neu EX447 PDF Testsoftware gegründet und gegründet wurde, je nachdem, ob Sie ein Branchenkenner oder eine IT-Kundenumgebung sind.

NEW QUESTION: 1

Which series of steps illustrates the correct flow for incident management?

- A.** Identify, categorize, prioritize, log, initial diagnosis, escalate, investigate and diagnose, resolve and recover, close
- B.** Categorize, log, identify, prioritize, initial diagnosis, escalate, investigate and diagnose, resolve and recover, close
- C.** Identify, log, categorize, prioritize, initial diagnosis, investigate and diagnose, escalate, resolve and recover, close
- D.** Identify, log, categorize, prioritize, initial diagnosis, escalate, investigate and diagnose, resolve and recover, close

Answer: D

Explanation:

The correct answer to this question is 1, however students often disagree with that answer choice. The rationale behind the answer is simply, "The correct order is given in the diagram in the incident management process, and in the subsections of [SO] 4.2.5." In this post, I will provide a better explanation of why choice a is the correct answer. First of all, the flow of activities in the incident management process is described in the Service Operation book section 4.2.5, and shown visually in Figure 4.3. Figure 4.3 shows the following flow of activities for incident management: As shown in Figure 4.3, the correct flow of activities in the incident management process begins with identification, which is followed by logging, which in turn is followed by categorization. Initial diagnosis occurs later in the process flow following prioritization. While the Service Operation book is clear about the flow of activities, the logic behind why the activities are in this order is not completely clear. Very few people disagree that the incident management process begins with identification, which in turn is followed by logging. The disagreement primarily exists in what follows logging, whether it is categorization or initial diagnosis. A good way to summarize the flow of activities is that they flow from general to specific. It often helps to clarify what the steps in the process do. Categorization allocates the type of incident that is occurring. In practice, organizations often use a multi-level categorization scheme, where the top-level consists of a few broad high-level categories. Subsequent levels of categorization might provide an additional level of detail. Practically, I've always thought of categorization as a way of identifying at a high-level what general area an

incident should belong to. For example, common top-level categories include things like "hardware", "software", "network", "user induced", "supplier induced", etc.. In fact, I once worked at a large organization that processes about 50,000 incident tickets per month with a set of 8 top-level categories. In other words, when categorization is done, we're really just trying to identify a general area to which the incident most likely belongs. Categorization can be revisited, and often changes throughout the lifecycle of an incident. Prioritization accounts for the impact and urgency of the incident and assigns a pre-defined code that guides an organization's response to an incident. In any population of incidents, an effective prioritization scheme tells the organization which incident to work on first. The ability to do this is critically important in high-volume environments where the organization has limited and shared resources capable of responding to numerous, simultaneous incidents. In other words, organizations have to make decisions about how to marshal resources based on their impact to the business and how quickly service must be restored. Initial diagnosis is described in the Service Operation book in section 4.2.5.5 as the activity where the service desk attempts to understand all symptoms of the incident in an effort to uncover what is wrong and attempt to correct it. During this activity, the service desk staff might use the known error database to speed incident resolution, or diagnostic scripts to identify the service fault. The logical reason why these steps are in this order is because during categorization and prioritization we try to uncover enough details about the incident so that it can be routed correctly throughout the process. For example, organizations might choose to handle hardware or network incidents differently than they handle software incidents. The same is true for prioritization. Prioritization seeks to establish facts about the incident in terms of its impact and urgency such that proper routing decisions can be made; for example, the highest priority is what is typically known as a "major incident", which will often follow a specific procedure dedicated to handling major incidents. Therefore, the early steps in the incident management process are focused on properly routing the incident. Knowing the category and priority help organizations make effective decisions about routing incidents. Improperly routed incidents will result in delayed resolution of service, which impacts users and customers and decreases satisfaction. For example, it would not make sense for a service desk to attempt initial diagnosis if they are not properly trained or equipped to investigate that category of incident. In fact, a service desk spending time doing initial diagnosis for incident categories where they are improperly trained and do not have effective scripts and tools will often result in delayed restoration of service, increased impact to users, and a negative impact to customer satisfaction. Clearly, according to ITIL, categorization occurs early in the incident management process, and there are good reasons why this is the case.

NEW QUESTION: 2

Which three steps are required to rekey the routers on a link without dropping OSPFv3 protocol packets or disturbing the adjacency? (Choose three.)

- A.** For every router on the link, create an additional inbound SA for the interface that is being rekeyed using a new SPI and the new key.
- B.** For every router on the link, create an additional outbound SA for the interface that is being rekeyed using a new SPI and the new key.
- C.** For every router on the link, remove the original inbound SA.

D. For every router on the link, replace the original inbound SA with one that uses the new SPI and key values.

E. For every router on the link, replace the original outbound SA with one that uses the new SPI and key values.

F. For every router on the link, remove the original outbound SA.

Answer: A,C,E

NEW QUESTION: 3

A. the Office attribute

B. the Member of attribute

C. Published Certificates

D. the Description attribute

Answer: B

NEW QUESTION: 4

You have a document in Microsoft OneDrive that is encrypted by using Microsoft Azure Information Protection as shown in the following exhibit.

Use the drop-down menus to select the answer choice that completes each statement based on the information presented in the graphic.

NOTE: Each correct selection is worth one point.

Answer:

Explanation:

Explanation:

Box 1:

If you copy the file from OneDrive to your internet connected computer, you can open the document for up to 30 days. This is because the "Number of days the content is valid" setting is set to 30 days.

Box 2:

If you email the document to a user outside your organization, the user cannot open the document. To open the document, the user would need to be added to the Users list and assigned permission. With the configuration in the exhibit, only the user listed in the Users list and the creator of the document can open the document.
